THE GREY SEAL, *HALichoerus Grypus* (FABRICIUS),
IN ROGALAND, NORWAY

By

Øystein Wiig
Institute of Marine Research, Bergen, Norway

ABSTRACT

Surveys of grey seals in Rogaland, southwestern Norway, are reviewed. The highest numbers of adult seals have been observed in the spring, while far less are generally observed during the breeding season in the autumn. Pupping has been recorded, but it is rare in relation to the number of seals observed in the spring. The nearest breeding site of grey seals in Norway is at Froan, about 680 km to the north. The southernmost recovery of pups tagged at Froan is about 300 km north of the pupping sites in Rogaland. There are many recoveries in western Norway of grey seal pups tagged in Great Britain. There is, however, no information suggesting that British seals are being recruited to Norwegian breeding stocks or are establishing new breeding colonies on the Norwegian coast. It is reasonable to assume that most of the grey seals found in Rogaland in the spring are British and return to Britain in the breeding season. It is not known whether the recorded breedings in Rogaland are stragglers from British colonies or relate to a local stock.

INTRODUCTION

The grey seal, *Halichoerus Grypus*, and the common seal, *Phoca vitulina* L., are the only resident seals on the Norwegian coast. Øynes (1964, 1966) surveyed the breeding colonies of both these species along the Norwegian coast and Summers, Bonner, and van Haaften (1978) estimated the total population of grey seals in Norway to be 2 000–3 000 seals.

A study of coastal seals and their interactions with inshore fisheries along the Norwegian coast from Stad (about 62°N) to Lofoten (about 68°N) was initiated by the Institute of Marine Research in 1974. The study was later extended to cover the larger part of the Norwegian coast. One result of this study is new information on the distribution and abundance of grey seals in Norway, summarized by Wiig (1986), who has also given a more detailed
account for Finnmark county (Wing 1987). The surveys indicate a minimum stock of 3100 grey seals in Norway.

Øynes (1966) was unable to verify any breeding of grey seals in southern Norway. The only reported breeding locality was at Kjør in Rogaland, where a couple of pups had been reported in some years.

Recent surveys indicate that more than 100 grey seals are found in Rogaland during parts of the year, and breeding has now been verified. There is, however, a disparity between the observed numbers of seals and the very few recorded births. This disparity may be related to an immigration of grey seals from Britain, which was recently reviewed by Bjorge and McConnell (1986).

The present paper gives a detailed account of recorded observations of grey seals in Rogaland, southwestern Norway, with a discussion of the status of the stock.

METHODS

The numbers of seals have been estimated from aerial and ground surveys carried out by the Sea Mammal Section of the Institute of Marine Research. The aerial surveys were made from twin-engined fixed-wing aircraft. In addition to direct counts, seals were photographed by 35-mm hand-held reflex-cameras, using colour reversal film as recommended by Vaughan (1971). The ground surveys were made from 12'-15' Zodiac inflatable boats, which are well suited for rapid landings on rocky shores and skerries, enabling the seals to be visually counted. In addition, observations have been reported by local fishermen.

In 1984 a culling program for seals in Rogaland permitted the killing of 25 grey seals. In fact, 15 were killed and the lower jaw, internal genitalia and stomach of each of 11 seals were sent to the Institute of Marine Research for further analysis. The animals were aged from tooth sections of the canine of the lower jaw, and their reproductive status were classified from the internal genitalia.

Three foetuses collected at Kjør in 1984 were weighed and their standard length (nose–tail) measured. Parturition dates were estimated from the relationship in Boyd (1984).

RESULTS

Seal observations in Rogaland are recorded in Table 1, and the localities are shown in Fig. 1. Surveys have been performed in February, March, May, June, October, November and December. Most of the grey seals were observed from February to June, and the largest aggregation was found at Kjør. Few adults and no pups have been observed during the surveys in the
breeding period from October to November. During the latest aerial survey (December 1985), only about 10 adult grey seals were observed at Kjør. In addition to these observations, surveys at Kjør were performed on several occasions by boat, during autumn 1985 (Table 2). Only a few adults and no pups were observed.

Most of the aged grey seals appeared to be young, and only two of eleven specimens were older than six years (Table 3). They were all shot in the autumn, but only two of the seven males were classified as mature. All four females, however, were pregnant or had given birth during the year of killing. Weight and standard length of the foetuses and the estimated parturition dates are given in Table 4.

In recent years, five white pups have been observed at Kjør (R. Roth pers. comm. to B. Bergflødt), in November/December 1983 one white pup was photographed at Higgilen near Kvitsøy (L. Reinertsen pers. comm.), one white pup was seen at Lausingen near Utsira on 22 August 1984. (O. Torstad pers. comm. to T. Ørlands), one white pup was observed at Kjør on 13 November 1984 (T. Ølberg pers. comm.), and a large pup, with remnants of white hairs, was seen at Higgilen near on Kvitsøy 2 January 1985 (L. Reinertsen pers. comm.).

**DISCUSSION**

Grey seals lived in Rogaland several thousand years ago (Wieg 1986). Archaeological excavations at "Vistehåå", a Stone Age site near Stavanger, have disclosed more than 200 bone remains from grey seals (Olsen 1976), which was the second most abundant species at the site. The site has been

dated to 8 000–6 000 B.P. by the Radiological Dating Laboratory, the Norwegian Institute of Technology, Trondheim, Norway (HUFFHAMMER pers. comm.). Pig (Sus scrofa L.) (49.5%) is the only species which has more abundant remains than the grey seal (13.0%). Only two other archaeological sites have grey seal remains of this abundance in Norway, these are the mesolithic sites «Kirkehelleren» at Træna and «Storbåthelleren» at Flakstadøy in Lofoten. According to DEGERBØL (1951) there is no doubt that grey seals bred in the neighbourhood of «Vistehåå». The site is situated only 2 km from Kjør, where grey seal pups have now been recorded.

The stock of grey seals in Rogaland was estimated to be 120 specimens in
stragglers suggest however, last 25 years support this. It is therefore uncertain occurs 1s uncertain.

Britain higher and norvégian taggings, immigration about 680 seals in the period from 1960 to 1981, the seals found in Rogaland to bi-cecling (1986). However, some seals breed in the period from 1973 to 1985. The southernmost recovery of these pups is at Florø, about 300 km north of Kjør (Wig and Øien in prep.).

Since tagging of grey seals in Great Britain was initiated in 1951, a total of 61 seals have been recovered in Norwegian coastal waters (Bjørges and Mcconnell, 1986). Fifty-eight of these were recovered within six months of tagging. Most of the recoveries were made on the western coasts from Rogaland to Sogn og Fjordane. According to Hickling, Rasmussen, and Smith (1962) and Hever (1974) this long distance dispersal is probably due to wind. The immigration from Great Britain is estimated to have been about 14300 seals in the period from 1960 to 1981, averaging about 650 grey seals pups per year (Bjørges and Mcconnell 1986). These correspond to a production of a stock of more than 2500 seals, which is more than 75% of the total Norwegian population of grey seals, according to the figures of Wig (1986). There is, however, no information suggesting that British grey seals are being recruited to Norwegian breeding stocks or are establishing new breeding colonies on the Norwegian coast. The few records of breeding in western Norway during the last 25 years support this. It is therefore uncertain where these seals actually breed when they become mature. According to the results of Norwegian taggings, the mature grey seals seem to return to their place of birth for reproduction (Wig and Øien in prep.). Some mixing between the stocks is, however, probable. This has been verified in Britain (Harwood et al. 1976) and in Canada (Mansfield and Beck 1977).

The numbers of grey seals observed in Rogaland in the spring is much higher than in the breeding season. It is reasonable, therefore, to assume that the seals found in Rogaland in the spring are British and that these return to Britain in the breeding season as also suggested by Bjørges and Mcconnell (1986). However, some seals evidently do breed in Rogaland, but it is uncertain whether these constitute a local stock or are just occasional young stragglers from the British stocks. The dated records of foetuses and pups suggest a pupping time in November and December in most of the cases. This is later in the year than along most of the Norwegian coast, where breeding occurs between September and November (Wig 1986).
ACKNOWLEDGEMENTS

I am grateful to J. Harwood, Sea Mammal Research Unit, Natural Environment Research Council, Cambridge, B. Bergflødt and T. Øritsland, Institute of Marine Research, Bergen, for commenting on the manuscript.
