Abstract: This article presents a Cramér-Rao lower bound for the discrete-time filtering problem under linear state constraints. A simple recursive algorithm is presented that extends the computation of the Cramér-Rao lower bound found in previous literature by one additional step in which the full-rank Fisher Information matrix is projected onto the tangent hyperplane of the constraint set. This makes it possible to compute the constrained Cramér-Rao lower bound for the discrete-time filtering problem without reparametrization of the original problem to remove redundancies in the state vector, which improves insights into the problem. It is shown that in case of a positive-definite Fisher Information Matrix the presented constrained Cramér-Rao bound is lower than the unconstrained Cramér-Rao bound. The bound is evaluated on an example.

1. INTRODUCTION

Discrete-time state estimation arise in adaptive control, identification as well as in model-based control, where it is usually prior to the control prediction step. In general, it is challenging to build an optimal estimator for such systems. Hence, it is necessary to turn to one of the many suboptimal filter techniques (Galdos, 1980).

A common strategy to design such an estimator is to use the Bayesian approach. Closed form solutions exist only for a few cases, and often it is necessary to approximate the Bayesian solution numerically. However, filters based on such approximations lead to estimates that deviate from the ideal solution (ˇSimandl et al., 2001). Lower bounds on the mean-square error of an estimate can give an indication of performance limitations. Consequently, it can be used to determine whether imposed performance requirements are realistic or not (Galdos, 1980; ˇSimandl et al., 2001; Tichavsky et al., 1998). The Cramér-Rao bound (CRB) given as the inverse of the Fisher information matrix (FIM) presents such a lower bound for dynamic models. However, in time-varying systems the estimated parameter vector (the estimated state vector) has to be considered random since it corresponds to an underlying non-linear, randomly driven model (Tichavsky et al., 1998).

In Van Trees (1968) the CRB was extended for random parameter estimation. The CRB was successfully applied in state estimation for discrete-time non-linear stochastic systems in Galdos (1980) and Bobrovsky and Zakai (1975). The basic principle for both bounds is to construct a suitable Gaussian system for which the mean-square estimation error is a lower bound to that of the original system. Another approach to compute the CRB for filtering problems in discrete-time non-linear systems was proposed by Tichavsky et al. (1998). They assume the state history as random parameter and obtain the CRB for the state as lower right block of the CRB for the complete state history (ˇSimandl et al., 2001). They referred to the obtained bound as posterior CRB (PCRB).

In some applications, prior knowledge in form of linear equality constraints is available. This information should result in improved estimates and a lower CRB (Marzetta, 1993). One way to find the CRB under constraints is to re-parametrize the original problem and remove redundancies in the parameter vector. However, this approach may be difficult to implement, and may hinder insights into the original unconstrained problem (Stoica and Ng, 1998).

Gorman and Hero (1990) proposed a convenient way to compute the constrained CRB for static problems. The bound equals the bound of the original unconstrained problem minus a correction matrix. The same result with a different proof was presented by Marzetta (1993). Another constrained CRB, which also holds for singular Fisher Information matrices, was presented by Stoica and Ng (1998). This theory was extended for complex parameters by Jagannatham and Rao (2004) and biased estimators by Ben-Haim and Eldar (2009).

This article connects the theory about constrained CRB with the PCRB for discrete-time systems presented by Tichavsky et al. (1998).

The article proceeds as follows: An overview over the PCRB is given in Section 2. In Section 3 the constrained CRB is introduced. How to compute the constrained CRB recursively is established in Section 4. In Section 5 it is proven that the constrained CRB is smaller or equal

2. THE CRB FOR THE NON-LINEAR FILTERING PROBLEM

This section follows mainly the posterior CRB presented in Tichavsky et al. (1998), which was also summarized in Šimandl et al. (2001). Consider the discrete-time non-linear filtering problem

\[ \begin{align*}
\mathbf{x}_{k+1} &= f_k(\mathbf{x}_k, \mathbf{w}_k) \\
\mathbf{z}_k &= h_k(\mathbf{x}_k, \mathbf{v}_k),
\end{align*} \]

(1a) (1b)

where \( k \) is the time index, and \( \mathbf{x}_k \in \mathbb{R}^n \) and \( \mathbf{z}_k \in \mathbb{R}^p \) represent the state and measurement vectors, respectively. The vectors \( \mathbf{w}_k \in \mathbb{R}^q \) and \( \mathbf{v}_k \in \mathbb{R}^p \) are mutually independent white processes and \( f_k \) and \( h_k \) are non-linear functions. They may depend on the time \( k \). The white noise processes are described by known probability density functions (pdf) \( p(\mathbf{w}_k) \) and \( p(\mathbf{v}_k) \). Furthermore, it is assumed that the initial state \( \mathbf{x}_0 \) has a known pdf \( p(\mathbf{x}_0) \).

Let the complete state and measurement histories up to the time instant \( k \) be denoted as \( \mathbf{X}_k = [\mathbf{x}_0^T, \mathbf{x}_1^T, \ldots, \mathbf{x}_k^T]^T \) and \( \mathbf{Z}_k = [\mathbf{z}_0^T, \mathbf{z}_1^T, \ldots, \mathbf{z}_k^T]^T \), respectively. The joint pdf of state and measurement histories \( p(\mathbf{X}_k, \mathbf{Z}_k) \) may be written as \( p(\mathbf{X}_k, \mathbf{Z}_k) = p(\mathbf{Z}_k|\mathbf{X}_k)p(\mathbf{X}_k) \). Respecting that, the stochastic system (1) is a Markov process, the logarithm of this pdf can be expressed as

\[ \ln p(\mathbf{X}_k, \mathbf{Z}_k) = \ln p(\mathbf{x}_0) + \sum_{i=0}^{k} \ln p(\mathbf{z}_i|\mathbf{x}_i) + \sum_{i=1}^{k} \ln p(\mathbf{x}_i|\mathbf{x}_{i-1}). \]

(2)

If the expectation and derivatives exist, the FIM for this system can be computed as

\[ \mathbf{J}_{k|k} (\mathbf{X}_k) = -E \left( \nabla_{\mathbf{X}_k} \nabla_{\mathbf{X}_k} \ln p(\mathbf{X}_k, \mathbf{Z}_k) \right)^T, \]

(3)

where we know that the mean-square error matrix (MSEM) is bounded by the inverse of the FIM

\[ \Sigma_{k|k} = E \left\{ (\mathbf{X}_k - \hat{\mathbf{X}}_k)(\mathbf{X}_k - \hat{\mathbf{X}}_k)^T \right\} \geq \mathbf{J}^{-1}_{k|k}. \]

(4)

Following the notation used in Šimandl et al. (2001) and in order to simplify the derivation of the filtering estimate let us introduce the following \( n \times n \) matrices

\[ \begin{align*}
\mathbf{K}^k_{k|k-1} &= E[-\nabla^2_{\mathbf{x}_k} \ln p(\mathbf{x}_k|\mathbf{x}_{k-1})], \\
\mathbf{K}^{k+1}_{k+1} &= E[-\nabla^2_{\mathbf{x}_{k+1}} \ln p(\mathbf{x}_{k+1}|\mathbf{x}_k)], \\
\mathbf{L}^k_1 &= E[-\nabla^2_{\mathbf{x}_k} \ln p(\mathbf{y}_k|\mathbf{x}_k)^T],
\end{align*} \]

(5a) (5b) (5c)

where we will define \( \mathbf{D}_k = \mathbf{L}^k_1 + \mathbf{K}^k_k + \mathbf{K}^k_{k+1} \).

The lower index in (5) is the time instant of the state described by the transition pdf, while the upper index represents the states for which the derivatives of the transition pdf are performed.

Using (2) and the introduced notations (5) the FIM (4) decomposes into four blocks

\[ \mathbf{J}_{k|k} (\mathbf{X}_k) = \begin{bmatrix} \mathbf{D}_0 & \mathbf{K}^{0,1}_1 \\
\mathbf{K}^{1,0}_1 & \ddots & \ddots \\
& \ddots & \ddots \\
& & \ddots & \mathbf{D}_{k-1} \\
\mathbf{K}^{k-1,k}_k & & & \mathbf{K}^{k-1,k}_k \\
\end{bmatrix}, \]

(7)

where the zero elements have been left empty and for \( k = 0 \) it holds \( \mathbf{J}_{0|0} (\mathbf{X}_0) = \mathbf{L}^0_0 + \mathbf{K}^0_0 \). The blocks of the FIM represent the state history decomposed as \( \mathbf{X}_k = [\mathbf{X}_{k-1}^T, \mathbf{x}_k^T]^T \). Following this notation, we can see that the time update can be expressed as (Šimandl et al., 2001)

\[ \begin{align*}
\mathbf{J}_{k+1|k} (\mathbf{X}_{k+1}) &= \begin{bmatrix} \mathbf{J}^{1,1}_{k+1|k} & \mathbf{J}^{1,2}_{k+1|k} & 0 \\
\mathbf{J}^{2,1}_{k+1|k} & \mathbf{J}^{2,2}_{k+1|k} + \mathbf{K}^k_{k+1} & \mathbf{K}^{k,k+1}_{k+1} \\
0 & \mathbf{K}^{k+1,k}_{k+1} & \mathbf{L}^{k+1}_k \\
\end{bmatrix},
\end{align*} \]

(8)

and the measurement update as

\[ \mathbf{J}_{k|k} (\mathbf{X}_k) = \begin{bmatrix} \mathbf{J}^{1,1}_{k|k} & \mathbf{J}^{1,2}_{k|k} & 0 \\
\mathbf{J}^{2,1}_{k|k} & \mathbf{J}^{2,2}_{k|k} + \mathbf{K}^k_k & \mathbf{K}^{k,k+1}_{k|k} \\
0 & \mathbf{K}^{k+1,k}_{k|k} & \mathbf{L}^{k}_k \end{bmatrix}. \]

(9)

The dimension of the FIM (8) and (9) increase at each iteration. Furthermore, it can be easily seen that \( \mathbf{J}_{k|k-1} (\mathbf{X}_k) \) and \( \mathbf{J}_{k|k} (\mathbf{X}_k) \) are equal except for the lower-right corner block, which is \( \mathbf{K}^k_k \) compared to \( \mathbf{K}^k_k + \mathbf{L}^k_k \).

Applying (4) to (9) a formulation for the inequality for the MSEF of a filtering estimate at time \( k \) can be obtained

\[ E \left\{ (\mathbf{x}_k - \hat{\mathbf{x}}_k)(\mathbf{x}_k - \hat{\mathbf{x}}_k)^T \right\} \geq \mathbf{C}^k_{k|k} = [\mathbf{J}^k_{k|k}(\mathbf{X}_k)]_{22}, \]

(10)

where \( \mathbf{C}^k_{k|k} \) is the PFB of an estimate \( \hat{\mathbf{x}}_{k|k} \). Using the matrix inversion lemma (A.1)-(A.2) and \( \mathbf{J}^{2,2}_{k|k-1} = \mathbf{K}^k_k \), we obtain

\[ \mathbf{C}^{-1}_{k|k} = \mathbf{L}^k_k + \mathbf{K}^k_k - \mathbf{J}^{2,1}_{k|k-1} \mathbf{J}^{1,1}_{k|k-1}^{-1} \mathbf{J}^{1,2}_{k|k-1}, \]

(11)

for the measurement update. For the time update with the same matrix inversion lemma the following can be obtained

\[ \mathbf{C}^{-1}_{k+1|k+1} = \mathbf{K}^{k+1}_{k+1} - \left( 0 \mathbf{K}^{k+1}_{k+1} \right) \mathbf{J}^{1,1}_{k+1|k+1} \mathbf{J}^{1,2}_{k+1|k+1}^{-1} \left( 0 \mathbf{K}^{k+1}_{k+1} \right), \]

(12)

With (11) and (12) the measurement update can also be reduced to

\[ \mathbf{C}^{-1}_{k|k} = \mathbf{C}^{-1}_{k|k-1} + \mathbf{L}^k_k, \]

(13)

which completes the recursion to compute the CRB for the time and measurement update.

3. CONSTRAINED CRB

In this section, the constrained CRB is introduced. This section will closely follow the derivation presented in Stoica and Ng (1998). However, the difference between this paper and Stoica and Ng (1998) is that Stoica and Ng (1998) assumed that a vector of non-random parameters...
is estimated. In this paper, on the other hand, a vector of random parameters $X$ based on a vector of observations $Z$ is estimated. It is required that the estimate $\hat{X}$ satisfies $I$ $(I < n)$ continuously differentiable constraints,

$$f(\hat{X}) = 0.$$  \hfill (15)

It is further assumed that the set $\{X|f(X) = 0\}$ is non-empty. The gradient matrix of the constraints can be defined as

$$\mathbf{F} = \frac{\partial f(X)}{\partial \hat{X}},$$  \hfill (16)

where it is assumed that (16) has full rank for any $X$ satisfying (15). Thus, there exist an $n \times (n - I)$ matrix $U$ such that

$$\mathbf{F} = 0, \quad U^T U = \mathbf{I},$$  \hfill (17)

where it is assumed that $U$ is independent of $X$. While this is restrictive, it always holds for linear constraints. The likelihood function is given by (2), and let us denote

$$\Delta = \nabla_X \ln p(X, Z),$$  \hfill (18)

In that case, the FIM (3) is alternatively given as

$$\mathbf{J} = E(\Delta \Delta^T).$$  \hfill (19)

If the following conditions exist

1. $\frac{\partial p(X|Z)}{\partial t} Z$ is absolutely integrable with respect to $X$ and $Z$ for $i = 0, \ldots, k$ and $j = 0, \ldots, n$,
2. $\frac{\partial^2 p(X|Z)}{\partial t^2} Z$ is absolutely integrable with respect to $X$ and $Z$ for $i = 0, \ldots, k$ and $j = 0, \ldots, n$,
3. The conditional expectation of the error, given $X$, is

$$\mathbf{B}(X) = \int_{-\infty}^{\infty} (X - \hat{X}) p(Z|X) dZ,$$  \hfill (20)

where $\mathbf{B}(X)$ denotes the bias of the estimate. It is assumed that

$$\lim_{t' \to \infty} \mathbf{B}(X)p(X) = 0, \quad \text{for } i = 0, \ldots, k$$ \hfill (21)

$$\lim_{t' \to \infty} \mathbf{B}(X)p(X) = 0, \quad \text{and } j = 0, \ldots, n.$$

With the conditions it can be shown that the following holds (Van Trees and Bell, 2013)

$$E((\hat{X} - X)(\hat{X} - X)^T) = \mathbf{I},$$  \hfill (22)

which is the fact that is required that such

$$E((\hat{X} - X)(\hat{X} - X)^T) = \mathbf{I}.$$  \hfill (23)

Lemma 1. If the condition holds, with $U$ defined in (17) and in case $U^T LJU$ is non-singular the constrained CRB is given as

$$E\{(X - \hat{X})(X - \hat{X})^T\} \geq U(U^T LJU)^{-1}U^T.$$  \hfill (24)

Proof. Let $W$ be an arbitrary $n \times n$ matrix. Then

$$E\{(X - \hat{X}) - WU^T \Lambda (X - \hat{X} - WU^T \Lambda)^T\} = E\{(X - \hat{X})(X - \hat{X})^T\} - WU^T W + WU^T LJU U^T W \succeq 0,$$  \hfill (25)

where the equality follows from (23) and the fact that $U$ is independent of $X$. The inequality is a consequence of the positive semi-definiteness of the covariance matrix of $X - \hat{X} - WU^T \Lambda$. For the rest of the proof the derivation in Stoica and Ng (1998) can be followed.

### 4. THE CONSTRAINED CRB FOR THE NON-LINEAR FILTERING PROBLEM

**Theorem 2.** The constrained CRB for the non-linear filtering problem can be computed by a time update

$$\mathbf{C}^{-1}_{k,k-1} = \mathbf{K}^k_k - \mathbf{K}^{k,k-1}_k \left( \mathbf{K}^{-1}_k + \mathbf{C}^{-1}_{k-1,k} \right)^{-1} \mathbf{K}^{-1}_{k-1,k},$$  \hfill (26)

a measurement update

$$\mathbf{C}^{-1}_{k,k} = \mathbf{C}^{-1}_{k-1,k} + \mathbf{I}^k_k;$$  \hfill (27)

and a constraint update

$$\mathbf{C}^{-1}_{k,k} = \mathbf{U}^T_k \mathbf{C}^{-1}_{k,k} \mathbf{U}^T_k.$$  \hfill (28)

**Proof.** It will be shown that the constrained CRB of the whole system (4) results in the same CRB as given by the recursion (26)-(28). This will be shown for the first time step and afterwards in will be shown that this holds also for every following time step.

The FIM for whole state and measurement history after the first time step is given by the following $2n \times 2n$ matrix

$$\mathbf{J}_{11|1}(X_1) = \begin{pmatrix} \mathbf{K}^0_0 + \mathbf{L}^0_0 + \mathbf{K}^1_1 & \mathbf{K}^0_1 + \mathbf{K}^1_1 \\ \mathbf{K}^0_1 + \mathbf{K}^1_1 & \mathbf{L}^1_1 + \mathbf{K}^1_1 \end{pmatrix}$$  \hfill (29)

It is assumed that the constraints (15) depend only on the states at each time step. This gives a $2n \times 2(n - I)$ matrix

$$\mathbf{U}(X_1) = \begin{pmatrix} \mathbf{U}(x_0) & 0 \\ 0 & \mathbf{U}(x_1) \end{pmatrix} = \begin{pmatrix} \mathbf{U}_0 & 0 \\ 0 & \mathbf{U}_1 \end{pmatrix},$$  \hfill (30)

where the matrix $U_k$ of each state is on the diagonal while all other entries are zero. Using (24), (30) and the matrix inversion lemma (A.1) on (29) to compute the constrained CRB for state $x_1$ we obtain

$$\mathbf{C}_{11|1} = \mathbf{U}_1^T \begin{pmatrix} \mathbf{L}^1_1 + \mathbf{K}^1_1 - \mathbf{K}^{-1}_{1,0} \left[ \mathbf{J}_{0|0} + \mathbf{K}^{-1}_{0|0} \right] \mathbf{U}_0^T \end{pmatrix} \mathbf{U}_1,$$  \hfill (31)

With the recursion (26)-(28) the constrained CRB for state $x_1$ is

$$\mathbf{C}_{11|1} = \mathbf{U}_1^T \begin{pmatrix} \mathbf{L}^1_1 + \mathbf{K}^1_1 - \mathbf{K}^{-1}_{1,0} \left[ \mathbf{J}_{0|0} + \mathbf{K}^{-1}_{0|0} \right] \mathbf{U}_0^T \end{pmatrix} \mathbf{U}^T_1.$$  \hfill (32)

Comparing (31) and (32) it can be seen that the only thing left to prove is

$$\mathbf{U}_0^T \left[ \mathbf{K}^0_0 + \mathbf{L}^0_0 + \mathbf{K}^1_1 \right]^{-1} \mathbf{U}_0^T \equiv \left[ \mathbf{J}_{0|0} + \mathbf{K}^{-1}_{0|0} \right]$$  \hfill (33)

The left-hand side of (33) is rewritten slightly and the binomial inverse theorem (B.1) applied

$$\mathbf{U}_0^T \left[ \mathbf{K}^0_0 + \mathbf{L}^0_0 \right]^{-1} \mathbf{U}_0^T = \mathbf{U}_0^T \left[ \mathbf{U}_0^T \left( \mathbf{K}^0_0 + \mathbf{L}^0_0 \right) \mathbf{U}_0 \right]^{-1} \mathbf{U}_0^T,$$

$$\left( I + \mathbf{K}_0 \mathbf{U}_0^T \left( \mathbf{K}^0_0 + \mathbf{L}^0_0 \right) \mathbf{U}_0 \right)^{-1} \mathbf{K}_0 \mathbf{U}_0^T,$$

$$\left( \mathbf{U}_0^T \left( \mathbf{K}^0_0 + \mathbf{L}^0_0 \right) \mathbf{U}_0 \right)^{-1} \mathbf{U}_0^T,$$  \hfill (34)

where $\mathbf{B} = \mathbf{U}_0^T, \mathbf{D} = \mathbf{K}_0$ and $\mathbf{C} = \mathbf{U}_0$. Given that

$$\left[ \mathbf{J}_{0|0} \right]^{-1} = \mathbf{U}_0^T \left( \mathbf{K}^0_0 + \mathbf{L}^0_0 \right) \mathbf{U}_0^{-1} \mathbf{U}_0^T.$$  \hfill (35)
the binomial inverse theorem (B.1) is also applied to the right-hand side of (33)
\[
\left[ J_{0|0} + K_0^0 \right]^{-1} = U_0 \left( U_0^T K_0^0 + L_0^0 \right) U_0^{-1} U_0^T \left( U_0^T K_0^0 + L_0^0 \right)^{-1} U_0^T \nabla_{0} (U_0^T (K_0^0 + L_0^0) U_0)^{-1} U_0^T,
\]
B \left( I + D C U_0 \left( U_0^T (K_0^0 + L_0^0) U_0 \right) B \right)^{-1} D C U_0
\]
\[
U_0 \left( U_0^T (K_0^0 + L_0^0) U_0 \right)^{-1} U_0^T,
\]
where B = I, D = K_0^0 and C = I. Comparing (34) and (36) we see that (33) holds.
For k time steps it can be obtained in a similar fashion as before (29) - (32) that
\[
U_{k-1} \left[ U_{k-1}^T \right]^{1 \cdot \cdot \cdot | k-1|} U_{k-1|0} U_{k-1|0} \equiv \left[ J_{k-1|k-1} + K_{k-1|k-1} \right]^{-1}.
\]
Applying the matrix inversion lemma to the left-hand side plus the fact that the matrix U is block-diagonal and setting in the recursive equations to the right-hand side, (37) can be reduced to (33).

5. REDUCTION OF THE CONSTRAINED CRB

In this section, it is established that the unconstrained CRB (4) is never smaller than the constrained CRB (24). Consequently, adding information about constraints reduces the CRB. This can be shown in case J_{k|k} is positive definite. In that case as shown in Stoica and Ng (1998); Khatari (1966) the constrained CRB (24) can be written as
\[
U(U^T J U)^{-1} U^T = (I - J^{-1} F^T (FJ^{-1} F^T)^{-1} F) J^{-1} = Q J^{-1},
\]
where F is given in (16) and indices and arguments were omitted for national convenience. It can be shown that Q is idempotent which means
\[
Q = Q Q.
\]
Furthermore, I - Q is idempotent and J^{-1} as well as QJ^{-1} are symmetric. With the conditions, it can be proven that the constrained CRB reduces in the sense that the subtraction of constraint from the unconstrained CRB is non-negative definite (Gorman and Hero, 1990).
\[
QJ^{-1} = J^{-1} - (I - Q)J^{-1} = J^{-1} - (I - Q)(I - Q)J^{-1} \leq J^{-1} - (I - Q)J^{-1} (I - Q)
\]
\[
(40)
\]

6. COMPUTATION OF THE CONSTRAINED CRB

The constrained CRB can be computed with the matrices (5) and the recursive equations (26) - (28). In case of a positive definite FIM J_{k|k} (28) can be exchanged with (38) which may reduce the computational burden. Important to consider is that the constrained CRB is singular. Consequently, the constrained CRB is not invertible. This is not an issue in the recursion, but (26) can only be computed with the help of a matrix inversion lemma like (A.3).

6.1 Linear Gaussian case

Let us consider the linear system with additive Gaussian state and measurement noise with linear equality constraints
\[
x_{k+1} = F_k x_k + w_k \quad (41a)
\]
\[
z_k = H_k x_k + v_k \quad (41b)
\]
\[
0 = A_k x_k \quad (41c)
\]
where A_k is the gradient matrix of the constraints. The process covariance and measurement covariance is given by the positive definite matrices Q_k and R_k, respectively. For this special case, the matrices (5) have an analytical solution
\[
\begin{align*}
R_{k+1}^T &= F_k^T Q_{k+1}^1 F_k, \\
R_{k+1}^T &= F_k^T Q_{k+1}^1 F_k, \\
K_{k+1}^T &= Q_{k+1}^1, \\
L_k^T &= H_k^T R_k^{-1} H_k.
\end{align*}
\]

Using the matrix inversion lemma (A.3) the recursive equations (26) and (27) can be computed as
\[
\begin{align*}
C_{k|k} &= Q_{k+1}^1 F_k^T, \\
C_{k|k} &= C_{k|k-1} - C_{k|k-1} H^T (R + H C_{k|k-1} H^T)^{-1} H C_{k|k-1},
\end{align*}
\]
with the Kalman filter time and measurement update equations (Simon, 2006). The constrained update step (28) should be computed using the right-hand side of (38)
\[
\begin{align*}
\tilde{C}_{k|k} &= C_{k|k} - C_{k|k-1} H^T (A_k C_{k|k} A_k^T)^{-1} A_k C_{k|k},
\end{align*}
\]
\[
\text{since it avoids the otherwise needed inversion of (43b)}.
\]

7. NUMERICAL EXAMPLE

In Simon (2010) a four state navigation problem with equality constraints is presented. The first two states present the positions and the last two states the velocities in north and east direction, respectively. The velocity of the vehicle is in the direction of \( \theta \), an angle measured anti-clockwise from the east axis. A sensor provides noisy measurement of the vehicle’s north and east positions. The equations for this system can be written as
\[
\begin{align*}
\begin{bmatrix}
1 & 0 & T \\
0 & 1 & 0 \\
0 & 0 & 1 \\
0 & 0 & 1
\end{bmatrix}
\begin{bmatrix}
x_k \\
y_k \\
\sin \theta \\
\cos \theta
\end{bmatrix}
&= \begin{bmatrix}
x_k^+ \\
y_k^+
\end{bmatrix}
+ \begin{bmatrix}
w_k \\
v_k
\end{bmatrix}
\]
\]
\[
\begin{bmatrix}
x_{k+1} \\
y_{k+1}
\end{bmatrix}
= \begin{bmatrix}
x_k \\
y_k
\end{bmatrix}
+ \begin{bmatrix}
w_k \\
v_k
\end{bmatrix}
\]
\[
\text{where } T \text{ is the discretization step size and } \mu_k \text{ is the acceleration input. The covariance of process and measurement noise are}
\]
\[
\begin{align*}
Q &= \text{diag}(4, 4, 1, 1), \\
R &= \text{diag}(900, 900)
\end{align*}
\]
\[
\text{and the initial estimation error covariance is}
\]
\[
P_0 = \text{diag}(900, 900, 4, 4),
\]
\[
\text{where it holds}
\]
\[
\begin{align*}
P_{0|0}^{-1} &= I_0^0 + K_0^0,
\end{align*}
\]
\[
\text{Since we know that the vehicle is on a road with a heading angle } \theta \text{ the following holds}
\]
\[
\begin{align*}
\tan \theta &= \frac{x(1) - x(3)}{x(2) - x(4)}
\end{align*}
\]
\[
The constraints of the system can be expressed in the form
\]
\[
D_1 = \begin{bmatrix}
1 - \tan \theta & 0 & 0 \\
0 & 0 & 1 - \tan \theta
\end{bmatrix}
\]
\[
\text{The constraints of the system can be expressed in the form}
\]
\[
D_2
\]
Fig. 1. Constrained and unconstrained CRB for the state components of the navigation example.

Fig. 2. Constrained CRB for the state components of the navigation example using either $D_1$ or $D_2$.

Fig. 3. Constrained CRB and error covariance of constrained Kalman filter (cKL) using system projection method. The system is constrained using $D_1$ or $D_2 = \begin{pmatrix} 0 & 0 & 1 \\ -\tan \theta & 0 & 0 \end{pmatrix}$. Consequently, the system has either one or two equality constraints.

The recursive equations (43)-(44) are used to compute the constrained CRB for the system with $D_1$ as constrained gradient matrix of the system. The CRB for all states is shown in Fig. 1. The CRB for the constrained system reduces since the constrained information is used to compute the bound. In a similar way the constrained CRB for the system using $D_2$ as gradient matrix of the constraints can be computed. Since $D_1$ provides more information about the constraints on the position while the same information as $D_2$ about the velocities, the constrained CRB using $D_1$...
Appendix A. MATRIX INVERSION LEMMA

The inverse of a 2 x 2 block matrix is given by

\[
\begin{pmatrix}
A & B \\
C & D
\end{pmatrix}^{-1} = \begin{pmatrix}
F^{-1} & -A^{-1}BE^{-1} \\
-D^{-1}CF & E
\end{pmatrix},
\]

(A.1)

where

\[
E = D - CA^{-1}B,
F = A - BD^{-1}C.
\]

(A.2)

Furthermore, the following holds

\[
(A + BDC)^{-1} = A^{-1} - A^{-1}B(D^{-1} + CA^{-1}B)^{-1}CA^{-1},
\]

(A.3)

provided \(A^{-1}\) exists.

Appendix B. BINOMIAL INVERSE THEOREM

The binomial inverse theorem is a more general formula of (A.3), which also exist in cases of a singular matrix D (Henderson and Searle, 1981)

\[
(A^{-1} + BDC)^{-1} = A^{-1} - A^{-1}B(I + DCA^{-1}B)^{-1}DCA^{-1}.
\]

(B.1)
