This paper deals with the problem of $L_2-L_\infty$ model reduction for continuous-time nonlinear uncertain systems. The approach of the construction of a reduced-order model is presented for high-order nonlinear uncertain systems described by the T-S fuzzy systems, which not only approximates the original high-order system well with an $L_2-L_\infty$ error performance level $\gamma$ but also translates it into a linear lower-dimensional system. Then, the model approximation is converted into a convex optimization problem by using a linearization procedure. Finally, a numerical example is presented to show the effectiveness of the proposed method.

1. Introduction

It is well known that fuzzy logic theory is an effective approach for the manipulation of complex nonlinear systems. Recently, it has witnessed the rapidly growing popularity of fuzzy control systems in practical applications. Among various kinds of fuzzy models, the Takagi–Sugeno (T-S) fuzzy model [1] is viewed as one of the most popular models. A number of IF-THEN rules, which describe the local input-output relationships of original nonlinear system, are introduced to this kind of model. The weighted sum of all local linear systems have been obtained by constructing a group of weight functions from the membership functions in each rule. This weighted sum is equivalent to the original nonlinear system, which can be regarded as a special kind of time-varying linear system. Thus, most of the classical linear control methods will be applicable. There are numerous cases in this approach. For example, stability analysis was investigated in [2–8], the controller design was presented in [9–18], state estimation and filtering problems were addressed in [19–23], and fault detection problem was widely studied in [24–26].

On the other hand, since high-dimensional complex mathematical modeling of physical systems and processes in many areas of engineering is frequently encountered, the problem of model reduction has obtained a considerable attention. This model brings severe hardship to analyze and synthesize the concerning systems. Therefore, it is desirable to find a possible lower-order model to approximate the original one without introducing significant performance error in real-word applications. There are many important reported results in the past decades. These have been developed to settle the difficulty of model approximation, such as the $L_2-L_\infty$ approach [27, 28], the $H_\infty$ (or equivalently, energy-to-energy) approach [29–32], the $H_2$ approach [33, 34], and the Hankel-norm approach [35]. Very recently, as the rapid developments of the linear matrix inequality [36–38] technique, this approach has been explored to settle the model reduction problem for different classes of systems in effect, involving time-delay systems [28], switched hybrid systems [30], and Markovian jump systems [39]. However, to the best of the authors’ knowledge, few results on $L_2-L_\infty$ model reduction for nonlinear uncertain systems described in the T-S fuzzy framework are available, and it still remains challenging. Thus, research in this area should be of both theoretical and practical importance, which motivates us to carry out the present work.
In this work, the $L_2$-$L_{\infty}$ model simplification problem is investigated for a class of nonlinear uncertain systems in the T-S fuzzy framework. For a given stable T-S fuzzy uncertain system, our attention is focused on the construction of reduced-order model, which approximates the original high-order system well in an $L_2$-$L_{\infty}$ error performance level $\gamma$. The rest of this paper is organized as follows. The problem formulation and some preliminaries are presented in Section 2. $L_2$-$L_{\infty}$ performance analysis and $L_2$-$L_{\infty}$ model reduction are given in Sections 3 and 4, respectively. A numerical example is provided in Section 5 and we conclude this paper in Section 6.

Notations. "T" stands for matrix transposition; $\mathbb{R}^n$ denotes the $n$-dimensional Euclidean space; the notation $P > 0$ means that $P$ is real symmetric and positive definite; $I$ and $0$ represent the identity matrix and a zero matrix, respectively; diag(...) stands for a block-diagonal matrix; $\| \cdot \|$ denotes the Euclidean norm of a vector and its induced norm of a matrix; and the signals that are square integrable over $[0, \infty)$ are denoted by $L_2[0, \infty)$ with the norm $\| \cdot \|_2$. In symmetric block matrices, we use an asterisk (*) to represent a term that is induced by symmetry. Matrices, if their dimensions are not explicitly stated, are assumed to be compatible for algebraic operations.

2. Problem Formulation and Preliminaries

In this paper, we consider a class of uncertain nonlinear systems which can be described by the following T-S fuzzy uncertain model.

2.1. Plant Form

Rule i. If $\theta_1(t)$ is $\mu_{i1}$ and $\theta_2(t)$ is $\mu_{i2}$ and ... and $\theta_p(t)$ is $\mu_{ip}$, then

$$\begin{align*}
\dot{x}(t) &= [A_i + \Delta A_i(t)] x(t) + [B_i + \Delta B_i(t)] u(t), \\
y(t) &= C_i x(t), \quad \forall t, \quad i = 1, 2, \ldots, r,
\end{align*}$$

(1)

where $\mu_{i1}, \ldots, \mu_{ip}$ are the fuzzy sets; $x(t) \in \mathbb{R}^n$ is the state vector; $u(t) \in \mathbb{R}^p$ is the input which belongs to $L_2[0, \infty)$; $y(t) \in \mathbb{R}^q$ is the output; $(A_i, B_i, C_i)$ are matrices of compatible dimensions, $r$ is the number of IF-THEN rules, $\theta_1(t), \theta_2(t), \ldots, \theta_p(t)$ are the premise variables; $\Delta A_i(t)$ and $\Delta B_i(t)$ are time-varying matrices with appropriate dimensions, which are defined as follows:

$$\begin{align*}
\Delta A_i(t) &= U_i F(t) M_i, \quad \Delta B_i(t) = U_i F(t) N_i, \\
& \forall t, \quad i = 1, \ldots, r,
\end{align*}$$

(2)

where $U_i, V_i, M_i$, and $N_i$ are known constant real matrices of appropriate dimensions and $F(t)$ is an unknown matrix function with Lebesgue-measurable elements and satisfies

$$F(t)^T F(t) \leq I, \quad \forall t, \quad i = 1, \ldots, r.$$

(3)

It is assumed that the premise variables do not depend on the input variables $u(t)$. Given a pair of $(x(t), u(t))$, the output of the T-S fuzzy systems with uncertainty is inferred as follows:

$$\begin{align*}
\dot{x}(t) &= \sum_{i=1}^r h_i(\theta(t)) \left\{ [A_i + \Delta A_i(t)] x(t) + [B_i + \Delta B_i(t)] u(t) \right\}, \\
y(t) &= \sum_{i=1}^r h_i(\theta(t)) C_i x(t), \quad \forall t,
\end{align*}$$

(4)

with

$$h_i(\theta(t)) = \frac{\nu_i(\theta(t))}{\sum_{j=1}^p \nu_j(\theta(t))}, \quad \nu_i(\theta(t)) = \prod_{j=1}^r \mu_{ij}(\theta_j(t)),$$

(5)

where $\mu_{ij}(\theta_j(t))$ is the grade of membership of $\theta_j(t)$ in $\mu_{ij}$. Suppose that $\nu_i(\theta(t)) \geq 0, i = 1, 2, \ldots, r, \sum_{i=1}^r \nu_i(\theta(t)) > 0$ for all $t$. Therefore, $h_i(\theta(t)) \geq 0$ for $i = 1, 2, \ldots, r$ and $\sum_{i=1}^r h_i(\theta(t)) = 1$ for all $t$.

Here, the system in (4) is approximated by a reduced-order uncertain system described by

$$\begin{align*}
\dot{\hat{x}}(t) &= [\hat{A} + \Delta \hat{A}(t)] \hat{x}(t) + [\hat{B} + \Delta \hat{B}(t)] u(t), \\
\hat{y}(t) &= \hat{C} \hat{x}(t), \quad \forall t,
\end{align*}$$

(6)

where $\hat{x}(t) \in \mathbb{R}^k$ is the state vector of the reduced-order system ($\hat{\Sigma}$) with $k < n$; it is assumed that $\Delta \hat{A}(t)$ and $\Delta \hat{B}(t)$ are time-varying matrices and have the structure of

$$\Delta \hat{A}(t) = \hat{U}(t) \hat{M}, \quad \Delta \hat{B}(t) = \hat{U}(t) \hat{N}, \quad \forall t,$$

(7)

with $F(k)$ being feasible. This assumption means that the uncertainties in both the original models and reduced order models should come from the same sources but with the different weighting matrices $[U_i, M_i, N_i]$ and $[\hat{U}, \hat{M}, \hat{N}]$. $\hat{A}, \hat{B}, \hat{C}, \hat{\bar{U}}, \hat{\bar{M}},$ and $\hat{\bar{N}}$ are appropriately dimensioned matrices to be determined later.

Augmenting the model in (4) to include the states in (6), we obtain the following error system as

$$\begin{align*}
\dot{\xi}(t) &= \sum_{i=1}^r h_i(\theta(t)) \left\{ [\bar{A}_i + \Delta \bar{A}_i(t)] \xi(t) + [\bar{B}_i + \Delta \bar{B}_i(t)] u(t) \right\}, \\
\epsilon(t) &= \sum_{i=1}^r h_i(\theta(t)) \bar{C}_i \xi(t), \quad \forall t,
\end{align*}$$

(8)
where \( \xi(t) = [x^T(t) \quad \tilde{x}^T(t)]^T \), \( e(t) = y(t) - \hat{y}(t) \), and

\[
\begin{align*}
\Delta \mathbf{A}_i &= \begin{bmatrix} A_i & 0 \\ 0 & \Delta A_i \end{bmatrix}, & \quad \Delta \mathbf{B}_i(t) &= \begin{bmatrix} \Delta A_i(t) & 0 \\ 0 & \Delta A(t) \end{bmatrix}, \\
\Delta \mathbf{C}_i &= \begin{bmatrix} C_i^T \\ -C'_i \end{bmatrix}, & \quad \Delta \mathbf{B}_i(t) &= \begin{bmatrix} \Delta B_i(t) \\ \Delta B_i(t) \end{bmatrix}.
\end{align*}
\]

(9)

Define

\[
\begin{align*}
\Delta \mathbf{A}_i(t) &= \mathbf{U}_i \tilde{F}(t) \mathbf{M}_i \\
\Delta \mathbf{B}_i(t) &= \mathbf{U}_i \tilde{F}(t) \mathbf{N}_i,
\end{align*}
\]

(10)

where

\[
\begin{align*}
\mathbf{U}_i &= \begin{bmatrix} U_i & 0 \\ 0 & \tilde{U}_i \end{bmatrix}, & \quad \mathbf{N}_i &= \begin{bmatrix} N_i \\ \tilde{N}_i \end{bmatrix}, \\
\tilde{F}(t) &= \begin{bmatrix} F(t) & 0 \\ 0 & F(t) \end{bmatrix}, & \quad \mathbf{M}_i &= \begin{bmatrix} M_i & 0 \\ 0 & \tilde{M}_i \end{bmatrix}.
\end{align*}
\]

Before proceeding, we introduce the following definitions, which will be of help in deriving our main results in the sequel.

**Definition 1.** The equilibrium \( \xi^* = 0 \) of T-S fuzzy uncertain system in (8) with \( u(t) = 0 \) is asymptotically stable if its solution \( \xi(t) \) satisfies

\[
\lim_{t \to \infty} ||\xi(t)||^2 = 0.
\]

(12)

**Definition 2.** Given a scalar \( \gamma > 0 \), the T-S fuzzy uncertain system in (8) is asymptotically stable with an \( L_2-L_\infty \) performance level \( \gamma \) if it is asymptotically stable when \( u(t) = 0 \) and, under zero initial condition and for all nonzero \( u(t) \in L_2[0, \infty) \), the following holds:

\[
\sup_{\mathbf{v} \in \mathbb{R}^n} \left[ \mathbf{v}^T(t) e(t) \right] < \gamma^2 \int_0^\infty u^T(t) u(t) \, dt.
\]

(13)

Therefore, the \( L_2-L_\infty \) model reduction problem addressed in this paper can be formulated as follows: given the high-order T-S fuzzy uncertain system in (4) and a scalar \( \gamma > 0 \), determine a reduced-order uncertain model in (6) such that the resulting error system in (8) is asymptotically stable with an \( L_2-L_\infty \) performance level \( \gamma \).

### 3. \( L_2-L_\infty \) Performance Analysis

Firstly, we investigate the asymptotic stability and \( L_2-L_\infty \) performance of the error system in (8) and have the following result.

**Theorem 3.** Given a scalar \( \gamma > 0 \), the error system in (8) is asymptotically stable with an \( L_2-L_\infty \) performance level \( \gamma \) if there exists matrix \( P > 0 \) such that for \( i = 1, 2, \ldots, r \),

\[
\begin{align*}
&\begin{bmatrix} P \mathbf{A}_i + \mathbf{A}_i^T P & P \mathbf{B}_i \mathbf{U}_i \mathbf{M}_i & 0 \\ * & -I & 0 \\ * & * & -\frac{1}{\mu} I \\ * & * & * & -\frac{1}{\mu} I \\
0 & 0 & 0 & \mathbf{N}_i^T \end{bmatrix} < 0, \\
&\begin{bmatrix} -P & -\mathbf{C}_i^T \\ * & -\gamma^2 \end{bmatrix} \leq 0.
\end{align*}
\]

(14)

(15)

**Proof.** Choose a Lyapunov function as

\[
V(\xi(t), t) \triangleq \xi^T(t) P \xi(t), \quad P > 0.
\]

(16)

Along the trajectories of the error system in (8), and considering the differential of the Lyapunov function in (16), we have

\[
\begin{align*}
\dot{V}(\xi(t), t) & = \sum_{i=1}^r h_i(\theta(t)) \left[ \left( \mathbf{A}_i + \Delta \mathbf{A}_i(t) \right) \xi(t) + \left( \mathbf{B}_i + \Delta \mathbf{B}_i(t) \right) u(t) \right]^T P \xi(t) \\
& \quad + \sum_{i=1}^r h_i(\theta(t)) \xi^T(t) P \left[ \left( \mathbf{A}_i + \Delta \mathbf{A}_i(t) \right) \xi(t) + \left( \mathbf{B}_i + \Delta \mathbf{B}_i(t) \right) u(t) \right] \\
& = \sum_{i=1}^r h_i(\theta(t)) \xi^T(t) \left[ P \left[ \mathbf{A}_i + \Delta \mathbf{A}_i(t) \right] \right. \\
& \quad + \left[ \mathbf{B}_i + \Delta \mathbf{B}_i(t) \right] u(t) \right] \\
& = \sum_{i=1}^r h_i(\theta(t)) \xi^T(t) \left[ P \left[ \mathbf{A}_i + \Delta \mathbf{A}_i(t) \right] \right. \\
& \quad + \left[ \mathbf{B}_i + \Delta \mathbf{B}_i(t) \right] u(t) \right].
\end{align*}
\]

(17)
Therefore, when assuming the zero input, that is, \(u(t) = 0\), we have from (17) that

\[
\dot{V}(\xi(t), t) = 0
\]

\[
= \sum_{i=1}^{r} h_i(\theta(t)) \dot{\xi}^T(t) \left\{ P \left[ \tilde{\Delta}_i(t) + \Delta \tilde{\Delta}_i(t) \right] \right\} \xi(t)
\]

\[
= \sum_{i=1}^{r} h_i(\theta(t)) \dot{\xi}^T(t) \left[ P \tilde{\Delta}_i(t) + \Delta \tilde{\Delta}_i(t) P \right] \xi(t)
\]

\[
\leq \sum_{i=1}^{r} h_i(\theta(t)) \dot{\xi}^T(t) \left[ P \tilde{\Delta}_i(t) + \Delta \tilde{\Delta}_i(t) P + \mu^{-1} P \tilde{u}_i^T(t) P \right] \xi(t)
\]

\[
\leq \sum_{i=1}^{r} h_i(\theta(t)) \dot{\xi}^T(t) \left[ P \tilde{\Delta}_i(t) + \Delta \tilde{\Delta}_i(t) P + \mu^{-1} P \tilde{u}_i^T(t) P \right] \xi(t).
\]

(18)

Inequality (14) implies that \(P \tilde{\Delta}_i(t) + \Delta \tilde{\Delta}_i(t) P + \mu^{-1} P \tilde{u}_i^T(t) P + \mu \tilde{M}_i^T \tilde{M}_i < 0\) by Schur complement, and thus \(V(\xi(t), t) < 0\). This implies that the error system in (8) with \(u(t) = 0\) is asymptotically stable.

Now, we will establish the \(L_2-L_{\infty}\) performance for the error system in (8). Assume zero initial condition, we have

\[
\dot{V}(\xi(t), t) - u^T(t) u(t)
\]

\[
= \sum_{i=1}^{r} h_i(\theta(t)) \dot{\xi}^T(t) \left\{ P \left[ \tilde{\Delta}_i(t) + \Delta \tilde{\Delta}_i(t) \right] \right\} \xi(t)
\]

\[
+ 2 \sum_{i=1}^{r} h_i(\theta(t)) \dot{\xi}^T(t) \left[ \tilde{\Delta}_i(t) \right] u(t) - u^T(t) u(t)
\]

\[
\leq \sum_{i=1}^{r} h_i(\theta(t)) \dot{\xi}^T(t) \left[ P \tilde{\Delta}_i(t) + \Delta \tilde{\Delta}_i(t) P + 2 \mu^{-1} P \tilde{u}_i^T(t) P \right. \\
\left. \quad + \mu \tilde{M}_i^T \tilde{M}_i \right] \xi(t)
\]

\[
+ 2 \sum_{i=1}^{r} h_i(\theta(t)) \dot{\xi}^T(t) \left[ P \tilde{u}_i(t) + \mu \tilde{u}_i^T(t) \tilde{u}_i(t) ight] u(t) - u^T(t) u(t)
\]

\[
\leq \sum_{i=1}^{r} h_i(\theta(t)) \left\{ \left[ \xi(t) \right]^T \left[ \begin{array}{ccc} Y_{11i} & Y_{12i} & \xi(t) \end{array} \right] \left[ u(t) \right] \right\}
\]

\[
(19)
\]
\( P > 0, \ Q > 0, \ A, \ B, \ C, \ D, \ U, \ M, \) and \( N \) such that for 
\( i = 1, 2, \ldots, r, \)

\[
\begin{bmatrix}
\Pi_{11i} & \Pi_{12i} & \Pi_{13i} & \Pi U_i & \Pi U_i & M_i^T & 0 & 0 & 0 \\
* & \Pi_{22} & \Pi_{23} & \Pi H_i & \Pi H_i & 0 & M_i^T & 0 & 0 \\
* & * & * & -I & 0 & 0 & 0 & N_i^T & N_i^T \\
* & * & * & * & -\frac{\mu}{2}I & 0 & 0 & 0 & 0 \\
* & * & * & * & * & -1I & 0 & 0 & 0 \\
* & * & * & * & * & * & -1I & 0 & 0 \\
* & * & * & * & * & * & * & -1I & 0 \\
\end{bmatrix} < 0,
\]

(26)

where

\[
\begin{bmatrix}
S_{11i} & S_{12i} & S_{13i} \\
* & S_{22i} & S_{23i} \\
* & * & S_{33i}
\end{bmatrix} \succeq 0,
\]

(27)

of generality, we assume that \( P_4 \) is nonsingular. To see this, let the matrix \( S \equiv P + \alpha T \), where \( \alpha \) is a positive scalar and

\[
T \equiv \begin{bmatrix}
0_{n \times n} & H \\
* & 0_{k \times k}
\end{bmatrix}, \quad S \equiv \begin{bmatrix}
S_1 & S_2 \\
* & S_3
\end{bmatrix},
\]

(31)

Observe that since \( P > 0 \), we have that \( S > 0 \) for \( \alpha > 0 \) in the neighborhood of the origin. Thus, it can be easily verified that there exists an arbitrarily small \( \alpha > 0 \) such that \( S_i \) is nonsingular and (14)-(15) are feasible with \( P \) replaced by \( S \). Since \( S_4 \) is nonsingular, we thus conclude that there is no loss of generality to assume the matrix \( P_4 \) to be nonsingular.

Define the following matrices which are also nonsingular:

\[
J \equiv \begin{bmatrix}
I & 0 \\
0 & P_3^{-1} P_4^T
\end{bmatrix}, \quad P_4 \equiv P_1, \quad \Theta \equiv P_2 P_3^{-1} P_4^T,
\]

(32)

\[
\begin{bmatrix}
A & B \\
C & D
\end{bmatrix} \equiv \begin{bmatrix}
P_4 & 0 \\
0 & I
\end{bmatrix}, \quad \begin{bmatrix}
A & B \\
C & D
\end{bmatrix}^{T} \equiv \begin{bmatrix}
A & B \\
C & D
\end{bmatrix}^T
\]

(33)

Performing a congruence transformation to (14) and (15) by \( \text{diag}(J, I) \) and \( \text{diag}(J, I) \), respectively, we obtain

\[
\begin{bmatrix}
J^T (P \tilde{A}_i + \tilde{A}_i^T P) J & J^T P \tilde{B}_i & J^T \tilde{U}_i & J^T M_i^T \\
* & -I & 0 & 0 \\
* & * & -\frac{\mu}{2}I & 0 & 0 \\
* & * & * & -1I & 0 \\
* & * & * & * & -1I
\end{bmatrix} < 0,
\]

(34)

where

\[
\begin{bmatrix}
\tilde{A} & \tilde{B} \\
\tilde{C} & \tilde{D}
\end{bmatrix} \equiv \begin{bmatrix}
A & B \\
C & D
\end{bmatrix}^T, \quad \begin{bmatrix}
\tilde{A} & \tilde{B} \\
\tilde{C} & \tilde{D}
\end{bmatrix} \equiv \begin{bmatrix}
A & B \\
C & D
\end{bmatrix}
\]

Moreover, if the above conditions are feasible, then the system 
matrices of an admissible reduced-order model in the form 
of (6) can be calculated from

\[
\begin{bmatrix}
\tilde{A} & \tilde{B} \\
\tilde{C} & \tilde{D}
\end{bmatrix} \equiv \begin{bmatrix}
A & B \\
C & D
\end{bmatrix}^T, \quad \begin{bmatrix}
\tilde{A} & \tilde{B} \\
\tilde{C} & \tilde{D}
\end{bmatrix} \equiv \begin{bmatrix}
A & B \\
C & D
\end{bmatrix}
\]

Proof: According to Theorem 3, \( P \) is nonsingular since \( P > 0 \). Now, partition \( P \) as

\[
P \equiv \begin{bmatrix}
P_1 & P_2 \\
P_3 & P_4
\end{bmatrix}, \quad P_1 \equiv \begin{bmatrix}
P_1 & P_2 \\
0_{(n-k) \times k}
\end{bmatrix},
\]

(30)

where \( P_1 \in \mathbb{R}^{n \times n} \) and \( P_3 \in \mathbb{R}^{k \times k} \) are symmetric positive definite matrices, \( P_2 \in \mathbb{R}^{n \times k} \), and \( P_4 \in \mathbb{R}^{k \times k} \). Without loss
Considering (36), we can obtain (26)-(27) from (34)-(35), respectively. Moreover, notice that (33) is equivalent to

\[
\begin{bmatrix}
\tilde{A} & \tilde{B} & \tilde{U}
\end{bmatrix}
\begin{bmatrix}
\tilde{C} & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\tilde{M} & 0 & \tilde{N}
\end{bmatrix}
\begin{bmatrix}
P_{4}^{-1} & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\tilde{A} & \tilde{B} & \tilde{U}
\end{bmatrix}
\begin{bmatrix}
\tilde{C} & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\tilde{M} & 0 & \tilde{N}
\end{bmatrix}
\]
\times
\begin{bmatrix}
P_{4}^{-T}P_{3} & 0 & 0
\end{bmatrix}
\begin{bmatrix}
0 & 1 & 0
\end{bmatrix}
\begin{bmatrix}
0 & 0 & I
\end{bmatrix}
\times
\begin{bmatrix}
(P_{4}^{-T}P_{3})^{-1} & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\tilde{A} & \tilde{B} & \tilde{U}
\end{bmatrix}
\begin{bmatrix}
\tilde{C} & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\tilde{M} & 0 & \tilde{N}
\end{bmatrix}
\times
\begin{bmatrix}
P_{4}^{-T}P_{3} & 0 & 0
\end{bmatrix}
\begin{bmatrix}
0 & 1 & 0
\end{bmatrix}
\begin{bmatrix}
0 & 0 & I
\end{bmatrix}
\times
\begin{bmatrix}
\tilde{A} & \tilde{B} & \tilde{U}
\end{bmatrix}
\begin{bmatrix}
\tilde{C} & 0 & 0
\end{bmatrix}
\begin{bmatrix}
\tilde{M} & 0 & \tilde{N}
\end{bmatrix}
\]  

(37)

Notice also that the matrices \(\tilde{A}, \tilde{B}, \tilde{C}, \tilde{U}, \tilde{M}, \) and \(\tilde{N}\) in (6) can be written as (37), which implies that \(P_{4}^{-T}P_{3}\) can be viewed as a similarity transformation on the state-space realization of the filter and, as such, has no effect on the filter mapping from \(u\) to \(\tilde{y}\). Without loss of generality, we may set \(P_{4}^{-T}P_{3} = I\), thus obtaining (29). Therefore, the filter \(\tilde{\Sigma}\) in (6) can be constructed by (29). This completes the proof. \(\square\)

Remark 5. Notice that the obtained conditions in Theorem 4 are all in linear matrix inequalities form; the fuzzy-rule-independent \(\mathcal{L}_2-\mathcal{L}_\infty\) model simplification can be determined by solving the following convex optimization problem:

\[
\min_{P > 0, Q > 0, A, B, C, M, N} \delta
\]

subject to (26)-(27) \(\) (where \(\delta = y^2\)).

5. Illustrative Example

Consider the continuous-time nonlinear uncertain system. The T-S fuzzy model of this nonlinear uncertain system is presented as follows.

5.1. Plant Form

Rule 1. IF \(x_1(t)\) is \(\mu_1\), then

\[
\dot{x}(t) = \begin{bmatrix} A_1 + \Delta A_1(t) \end{bmatrix} x(t) + \begin{bmatrix} B_1 + \Delta B_1(t) \end{bmatrix} u(t),
\]

\[
y(t) = C_1 x(t).
\]

Rule 2. IF \(x_1(t)\) is \(\mu_2\), then

\[
\dot{x}(t) = \begin{bmatrix} A_2 + \Delta A_2(t) \end{bmatrix} x(t) + \begin{bmatrix} B_2 + \Delta B_2(t) \end{bmatrix} u(t),
\]

\[
y(t) = C_2 x(t),
\]

where

\[
\Delta A_1(t) = \begin{bmatrix} -0.02 \sin(t) & 0.03 \sin(t) & -0.04 \sin(t) & 0.02 \sin(t) \\
0.04 \sin(t) & -0.06 \sin(t) & 0.08 \sin(t) & -0.04 \sin(t) \\
0.02 \sin(t) & -0.03 \sin(t) & 0.04 \sin(t) & -0.02 \sin(t) \\
-0.06 \sin(t) & 0.09 \sin(t) & -0.12 \sin(t) & 0.06 \sin(t) \\
\end{bmatrix},
\]

\[
\Delta A_2(t) = \begin{bmatrix} 0.02 \sin(t) & -0.02 \sin(t) & 0.04 \sin(t) & -0.06 \sin(t) \\
-0.01 \sin(t) & 0.01 \sin(t) & -0.02 \sin(t) & 0.03 \sin(t) \\
0.02 \sin(t) & -0.02 \sin(t) & 0.04 \sin(t) & -0.06 \sin(t) \\
0.04 \sin(t) & -0.04 \sin(t) & 0.08 \sin(t) & -0.12 \sin(t) \\
\end{bmatrix},
\]

\[
\Delta B_1(t) = \begin{bmatrix} 0.05 \sin(t) \\
-0.10 \sin(t) \\
-0.05 \sin(t) \\
0.15 \sin(t) \\
\end{bmatrix},
\]

\[
\Delta B_2(t) = \begin{bmatrix} -0.04 \sin(t) \\
0.02 \sin(t) \\
-0.04 \sin(t) \\
-0.08 \sin(t) \\
\end{bmatrix},
\]

\[
A_1 = \begin{bmatrix} -2.2 & 0.2 & 0.2 & 0.1 \\
0.2 & -4.2 & 0.2 & 0.1 \\
0.3 & 0 & -3.1 & 0.2 \\
0.4 & 0.2 & 0.1 & -1.5 \\
\end{bmatrix},
\]

\[
B_1 = \begin{bmatrix} 2.4 \\
1 \\
1.3 \\
2 \\
\end{bmatrix},
\]

\[
A_2 = \begin{bmatrix} -2.5 & 0.1 & 0.3 & 0.2 \\
0.2 & -4.1 & 0.1 & 0.2 \\
0.1 & 0 & -2.9 & 0.2 \\
0.4 & 0.2 & 0.1 & -1.7 \\
\end{bmatrix},
\]

\[
B_2 = \begin{bmatrix} 2.2 \\
1.1 \\
1.2 \\
2.1 \\
\end{bmatrix},
\]

\[
C_1 = \begin{bmatrix} 1 & 1.1 & 0.6 & 0.3 \end{bmatrix},
\]

\[
C_2 = \begin{bmatrix} 1.1 & 1.5 & 0.3 \end{bmatrix}.
\]

Here, we are interested in finding reduced-order systems (Case 1: \(k = 3\); Case 2: \(k = 2\); Case 3: \(k = 1\)) in the form of \(\tilde{\Sigma}\) in (6) to approximate the above system in an \(\mathcal{L}_2-\mathcal{L}_\infty\) sense by using the convex linearization. Solving the (26)-(29) in Theorem 4, we have the results for different cases shown as follows.

Case 1. with \(k = 3\), the minimum \(\gamma\) is \(\gamma^* = 0.5367\) and

\[
\mathcal{P} = \begin{bmatrix}
80.5202 & 78.7268 & -79.2386 & -2.3421 \\
78.7268 & 116.0219 & -75.9371 & -0.4125 \\
-79.2386 & -75.9371 & 93.7412 & 3.0132 \\
-2.3421 & -0.4125 & 3.0132 & 0.8390
\end{bmatrix},
\]

\[
\mathcal{Q} = \begin{bmatrix}
66.0499 & 77.0315 & -54.9810 \\
77.0315 & 114.8214 & -72.8165 \\
-54.9810 & -72.8165 & 50.6632
\end{bmatrix},
\]

\[
\begin{bmatrix}
\tilde{A} & \tilde{B} & \tilde{U} \\
\tilde{C} & 0 & 0 \\
0 & 0 & \tilde{N}
\end{bmatrix}
\]

\[
= \begin{bmatrix}
-0.9192 & 1.7384 & -3.0426 & -2.2476 & -0.0127 \\
1.1148 & -2.4321 & -2.3040 & -0.9573 & -0.0363 \\
2.9105 & 4.0517 & -10.1880 & -1.0748 & -0.0679 \\
-2.2244 & -1.2487 & 1.2255 & 0.0000 & 0.0000 \\
-0.0334 & 0.0501 & -0.0667 & 0.0000 & 0.0834
\end{bmatrix}.
\]
Table 1: Achieved $\gamma^*$ for the obtained reduced-order models.

<table>
<thead>
<tr>
<th>Reduced-order model</th>
<th>$k = 3$</th>
<th>$k = 2$</th>
<th>$k = 1$</th>
</tr>
</thead>
<tbody>
<tr>
<td>Optimal $\mathcal{L}<em>2$-$\mathcal{L}</em>\infty$ performance</td>
<td>$\gamma^* = 0.5367$</td>
<td>$\gamma^* = 0.5459$</td>
<td>$\gamma^* = 0.6652$</td>
</tr>
</tbody>
</table>

Case 2. with $k = 2$, the minimum $\gamma$ is $\gamma^* = 0.5459$ and

$$P = \begin{bmatrix} 23.1397 & 14.2678 & -10.3622 & -2.1777 \\ 14.2678 & 41.5106 & 1.5331 & -0.0137 \\ -10.3622 & 1.5331 & 14.6263 & 2.0607 \\ -2.1777 & -0.0137 & 2.0607 & 0.9969 \end{bmatrix}$$

$$Q = \begin{bmatrix} 14.9535 \\ 15.2591 \end{bmatrix}$$

(44)

$$\begin{bmatrix} \hat{A} & \hat{B} & \hat{U} \\ \hat{C} & 0 & 0 \\ M & 0 & N \end{bmatrix} = \begin{bmatrix} -2.0175 & 0.2412 & -2.2984 & 0.0189 \\ 0.4053 & -3.9994 & -1.0161 & -0.0120 \\ -1.6650 & -1.0603 & 0.0000 & 0.0000 \\ -0.0216 & 0.0325 & 0.0000 & 0.0541 \end{bmatrix}$$

(45)

Case 3. with $k = 1$, the minimum $\gamma$ is $\gamma^* = 0.6652$ and

$$Q = \begin{bmatrix} 13.8424 \end{bmatrix}$$

(46)

$$\begin{bmatrix} \hat{A} & \hat{B} & \hat{U} \\ \hat{C} & 0 & 0 \\ M & 0 & N \end{bmatrix} = \begin{bmatrix} -2.0108 & -2.3112 & 0.0072 \\ -2.0181 & 0.0000 & 0.0000 \\ -0.0144 & 0.0000 & 0.0361 \end{bmatrix}$$

(47)

In Table 1, the achieved $\gamma^*$ for different cases can be arranged by solving the convex optimization problem, as discussed in Remark 5.

In addition, to show the model reduction performances of the obtained reduced-order systems, let the initial condition be zero, that is, $\bar{x}(0) = 0$ ($x(0) = 0$, $\hat{x}(0) = 0$), and suppose the membership functions to be

$$h_1 (x_1 (t)) = \exp \left[ -\frac{\dot{x}_1 (t) - \theta}{2\sigma^2} \right],$$

$$h_2 (x_1 (t)) = 1 - \exp \left[ -\frac{\dot{x}_1 (t) - \theta}{2\sigma^2} \right],$$

(48)

which are shown in Figure 1, and the exogenous input $u(t)$ is

$$u (t) = \exp (-0.7t) \sin (2t), \quad t \geq 0.$$

(49)

Figure 2 shows the outputs of the original system (39)-(40) (black line), the third-order reduced model (43) (red line), the second-order reduced model (45) (blue line), and the first-order reduced model (47) (green line) due to the above input signal. The output errors between the original system and the reduced models are shown in Figure 3.

6. Conclusions

In this paper, the $\mathcal{L}_2$-$\mathcal{L}_\infty$ model reduction problem has been solved for T-S fuzzy uncertain systems by employing the convex linearization approach. Sufficient conditions of T-S fuzzy uncertain system have been proposed for the asymptotic stability with an $\mathcal{L}_2$-$\mathcal{L}_\infty$ performance of the approximation error. The corresponding solvability conditions for the reduced-order models by using the convex linearization approach have been derived. The presented numerical example has shown the utility of the proposed model approximation method. This paper talks about the model reduction problem for nonlinear systems by...
employing the convex linearization approach. In order to achieve more practical oriented results, further work could be considered under data-driven (measurements) framework [40, 41]. The future topics, for example, control [42] and fault tolerant scheme [43] in the identical framework seem more interesting from both academic and industrial domains.

Conflict of Interests

The authors declare that there is no conflict of interests regarding the publication of this paper.
